

FOR PV OWNERS RUNNING HOME ASSISTANT OR NODE-RED

It's overcast. **How warm is the water already?**

Your geyser is the biggest discretionary load in the house, and the only one your automation cannot see. So the six o'clock run happens anyway, and it comes out of the battery. At midday there is surplus to spend, and no way to tell how much heat the water already holds.

GeyserSense reads the probe in your geyser's thermostat and gives your automation the number, every 30 seconds. It composes with the switching you already have. Your contactor or smart switch stays exactly where it is. No app to install: the interface is served from the unit's own flash.

Shown fitted in an IP66 enclosure with two cable glands.

ACCURACY	±0.5 °C over 39.95–76.20 °C, measured against a PT100 reference
READING	Every 30 s · 16-bit, ratiometric, from the thermostat's own NTC probe
REACHES YOU BY	MQTT with Home Assistant Discovery · read-only JSON over your LAN · mDNS
DEPENDS ON	Your network. No cloud, no account, no subscription

WHAT YOUR AUTOMATION CAN DO ONCE IT CAN SEE

Spend surplus, not battery. Heat while the array is making more than the house needs, and leave the early run alone unless the water actually needs it.	Skip the cycle nobody used. Still at 55 °C from yesterday because nobody showered. That is an hour of stored energy you get to keep.	Stop at a temperature, not a clock. End the run when the water is where you want it, not when the clock says so.
---	--	--

THE RECORD

And it remembers the over-heating **you never saw**.

Water cools. When the geyser's cut-out trips, the first anyone knows is a cold shower. By then the over-heating has gone, and nothing was watching for it.

GeyserSense is watching. It writes down the hottest the water has been, when that happened, and how often it has gone over the limit you set. The record survives a power cut, and only you can clear it. The unit puts it on the home screen without being asked.

HOW IT FITS WHAT YOU ALREADY RUN

GeyserSense sits on the reading path only, so a failed sensor costs you visibility and nothing else.

BEFORE YOU BUY

Your automation becomes the thermostat.

The Geyserwise GEY013 this sensor reads **replaces your existing thermostat**, and it does not regulate: no dial, no setpoint. It senses, and trips on over-temperature at a marked 90 °C. After fitting, **your rules are the only thing deciding how hot the water gets**. If you would rather your geyser regulate itself in hardware, this is the wrong product for you.

The GEY013 stem thermostat. The black lead is the probe this sensor reads.

WHAT IT DOES NOT DO, SO NOBODY BUYS THE WRONG THING

— It does not control the geyser. No relay, no setpoint, no authority over the element.	— It does not promise a saving. The saving belongs to your rules; the sensor supplies the number.
— It does not detect a tripped cut-out. It reports the over-heating that usually precedes one.	— It does not make the geyser safer. It is worth having for what it shows you, never for safety.
